Television Media Table Dumps

Overview
This document records the completion of Sprint 8 – Tertiary Dump. The goal of this sprint is to generate validated SQL structure + data dumps for the following tables to preserve their current state prior to cleanup or consolidation activities: State, non_subscriber, image_recognition, image_recognition_video.

1. Tasks

Task 1: Create a database dump and store it in GitHub

Generate SQL dumps of assigned tables, name them using the agreed convention, and store them in the team repository.

Actions Taken:

- SQL dumps were generated for the following tables:
    - State
    - non_subscriber
    - image_recognition
    - image_recognition_video

The goal of this task was to generate and validate SQL dumps for the assigned tables and review timestamp/date fields (where applicable) to preserve the current state of the data prior to any schema cleanup, retention review, or stored procedure refactoring.

Task 2: Identify and classify large vs. small tables

Review table sizes and identify large tables (e.g., SRT, audio, debug tables). Some tables have millions of records to sort. Confirm which tables qualify as small tables suitable for full data dumps. Record table classification for reference.

Actions Taken:

- Table sizes were reviewed prior to exporting data.

- The following classifications were determined:

Result:
All the tables were classified as small, and therefore suitable for full structure + data dumps.

Task 3: Validate table data retention window

Verify that tables do not contain data older than the agreed retention period.

Actions Taken:

- Timestamp fields were reviewed for all assigned television media tables prior to finalizing SQL dumps.

- The following findings were observed:

    - **State** - Has critical data and doesn't have a time stamp.
    - **non_subscriber** - Has no data
    - **image_recognition** - Has no data
    - **image_recognition_video** - Has no data

Task 4: Split the database dump into two logical dumps

Separate schema and data into logical dump groupings.

Actions Taken:

- Table schemas were stored in a dedicated structure folder.
- Table data was stored in a dedicated data folder.
- Each table was exported independently to improve traceability.

Result:
Schema and data were logically separated and clearly organized.

Task 5: Extract and download data that should not be dumped

Identify data unsuitable for SQL dumping due to size or sensitivity.

Actions Taken:

- All assigned television media tables were reviewed prior to finalizing SQL dumps.
- No fields indicating direct PII (email/name/phone/token columns) were found in the provided schemas.
- Given the sizes and row counts, no data required separate extraction.

Result:
No exclusions or separate downloads were required for this user story.

Task 6: Escalate retention violations if found

Notify the sponsor or backend team if retention violations are identified.

Actions Taken:

- The following retention-related findings were observed from the provided query results:
- State contains only 2 rows but this is critical reference data and is not subject to deletion under the 90-day retention policy.
- non_subscriber, image_recognition, and image_recognition_video contain 0 rows, so no outdated records can exist in the current dataset.
- The assigned tables do not contain native DATE/DATETIME/TIMESTAMP fields, so retention evaluation is not directly applicable within these tables for this sprint.
- No deletion or modification of production data was performed during this sprint to avoid unintended data loss.

Result:
No escalation was required because there were no records older than 90 days present in the assigned tables.

Task 7: Document findings, changes, and justifications

Document dump strategy, findings, and justification.

Actions Taken:

- Dump strategy, table classification, retention review, and validation steps are documented in this report.

- File naming conventions and storage locations were recorded for traceability.

Result:
All documentation requirements were met, completing Task 7.

2. Tests

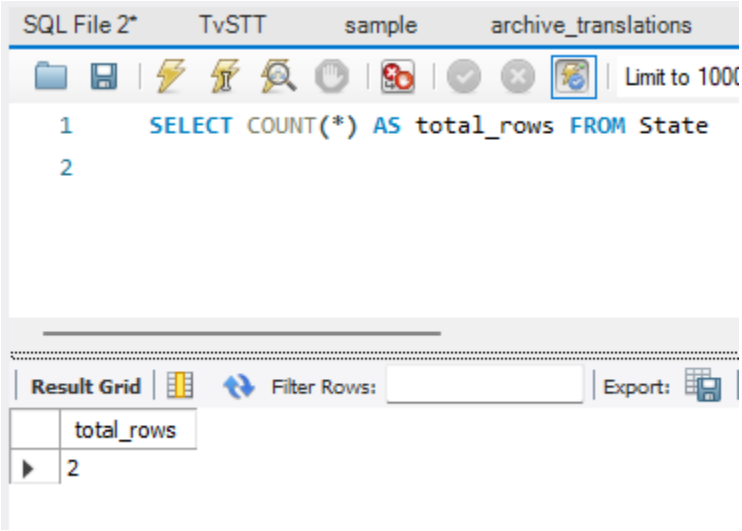
Test Scenario 1: Confirm Table Qualifies to be Dumped

Verify that tables selected for dumping do not contain data that must be retained elsewhere.

Validation Performed:

- Tables were reviewed for size, sensitivity, and usage.

- All selected tables were confirmed appropriate for SQL dumping.

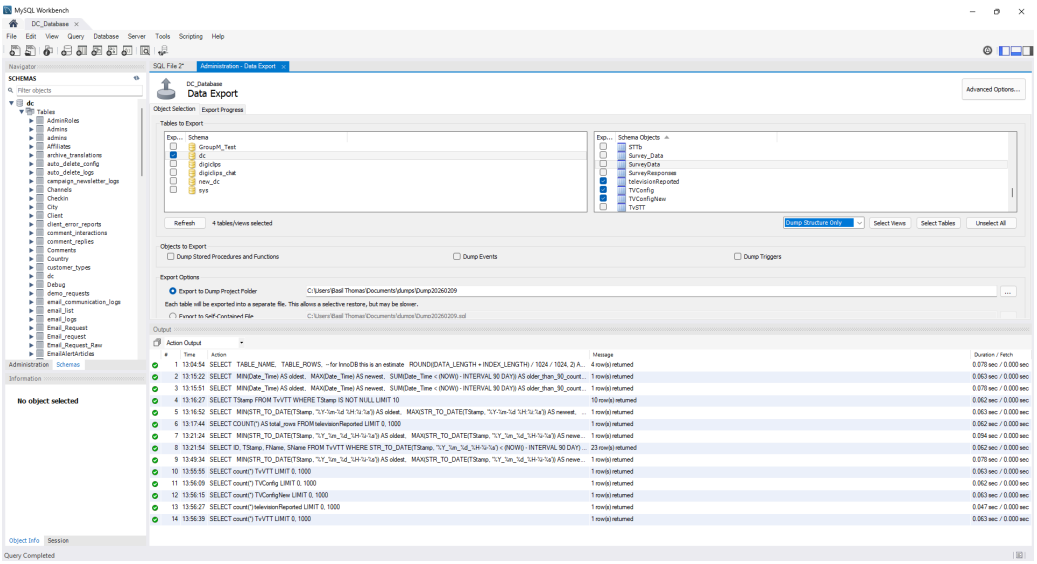


Test Scenario 2: Verify Tables to be Dumped

Confirm selected tables with DigiClips before executing dumps.

Validation Performed:

- Table selection followed Sprint 7 Planning Agreement and prior documentation.
- No critical data loss risk was identified.

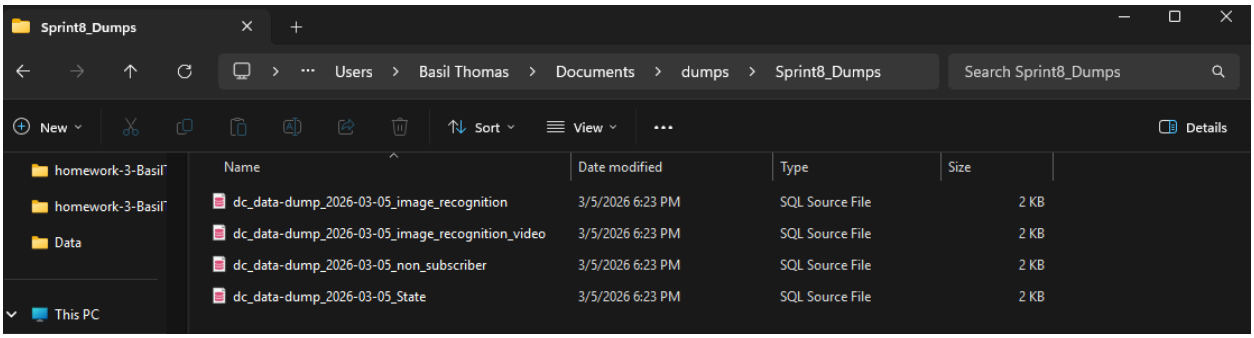


Test Scenario 3: Verify Tables to be Downloaded

Confirm that any necessary data is preserved appropriately.

Validation Performed:

- No tables required alternative data storage.
- SQL dumps were sufficient for all assigned tables.



Test Scenario 4: Verify Age of Web-Scraped Data

Ensure web-scraped data is within retention limits.

Validation Performed:

- Verified whether the assigned tables contain any DATE/DATETIME/TIMESTAMP fields used for retention evaluation.
- Verified whether the assigned tables contain any records that could represent web-scraped data to evaluate.
- Reviewed image_recognition.video_timestamp and confirmed it is stored as a non-date field (VARCHAR) and does not provide a direct created/collected date for 90-day validation.

Results:

- Date/timestamp columns found: None
- Row counts:
  - State: 2 rows (reference values, not web-scraped content)
  - non_subscriber: 0 rows
  - image_recognition: 0 rows
  - image_recognition_video: 0 rows

SQL File 2* | TvSTT | sample | archive_translations | Administration - Data Export | State

Limit to 1000 rows

```sql
SELECT 'State' AS table_name, COUNT(*) AS total_rows FROM State
UNION ALL
SELECT 'non_subscriber', COUNT(*) FROM non_subscriber
UNION ALL
SELECT 'image_recognition', COUNT(*) FROM image_recognition
UNION ALL
SELECT 'image_recognition_video', COUNT(*) FROM image_recognition_video;
```

Result Grid | Filter Rows: | Export: | Wrap Cell Content:

table_name	total_rows
State	2
non_subscriber	0
image_recognition	0
image_recognition_video	0

Conclusion:

- No web-scraped records exist in the current state of the assigned tables, and no retention-relevant timestamp fields exist within these tables.
- Therefore, no records older than 90 days were identified, and no retention-based dumping or escalation was required for this scenario.
